Method and Device for Welding Two Bodies Together

Assistant Commissioner for Patents Washington, D.C. 20231

Sir:

Please enter the following Preliminary Amendment into the above-mentioned application.

Preliminary Amendment

In the claims:

Please amend claim 5 as follows.

(once amended) Method for welding together two pipes as claimed in claim 1, 5. characterized in that each carrier is moved per welding pass over half a peripheral part of the pipes.

Remarks

The preliminary amendment is used to eliminate multiple dependent claims by amending claim 5 of the annexes.

Respectfully submitted,

Mark Zovko

Marked Up Version of Revised Claim Showing Changes

Method for welding together two pipes as claimed in [any of the preceding claims] <u>claim 1</u>, characterized in that each carrier is moved per welding pass over half a peripheral part of the pipes.

JC17 Rec'd PCT/PTO 0 1 AUG 2001 PCT/NL00/20072 09/890725

1

METHOD AND DEVICE FOR WELDING TOGETHER TWO BODIES

The present invention relates to a method for welding together two bodies, for instance pipes or plates, which are placed mutually in line against each other while leaving clear a weld groove, wherein the weld groove is filled with more than one welding layer by means of a welding torch moved in longitudinal direction of the weld groove. The present invention also relates to a device for welding together two bodies, for instance pipes or plates, which are placed mutually in line against each other while leaving clear a weld groove, comprising at least one carrier for a welding torch guidable in longitudinal direction of the weld groove.

It is generally known to realize connections between two pipes, for instance to form a pipeline, or two plates by means of welding. Since the maximum thickness of a welding layer which can be deposited is limited and the pipes or plates are often too thick to be connected with a single welding layer, a welded connection is built up by laying several welding layers over each other until the weld groove is wholly filled. A method and device suitable for this purpose is known from the Netherlands patent application 9400742.

The present invention has for its object to improve the above stated method and device.

The method according to the invention is characterized for this purpose in that two welding layers are laid in one welding pass by means of two welding torches placed successively on a carrier in the longitudinal direction of the weld groove. A time-saving is hereby obtained in the welding process. This is of particular importance in applications where the welding time is of great economic influence, such as is the case in laying pipelines. Particularly in the use aboard a pipelaying vessel, a short welding time is important in

achieving a high production in the number of welded connections per day with a limited number of welding devices. This is because the number of welding devices is limited by the dimensions of the ship.

If the weld groove has outward diverging walls, at least the trailing torch preferably performs an oscillating movement. A wider welding layer can hereby be laid by the trailing welding torch.

When the weld groove is filled with two welding

10 layers in only one welding pass, oscillation of only the
trailing welding torch can suffice. If on the other hand
the weld groove is filled in several welding passes, both
the leading and trailing welding torch are then
oscillated. In this latter case the trailing welding

15 torch is preferably oscillated at a greater amplitude

than the leading welding torch, so that the width of the welding layer to be deposited per welding pass by each welding torch can be adjusted to the width of the weld groove.

In order in this case to enable complete filling of the weld groove with welding material, more welding material can be added to the trailing welding torch, although the trailing welding torch can also be oscillated at a different, preferably higher, frequency

- 25 than the leading welding torch. The weld width of the two successive welding layers is separately controlled in that both the amplitude and the frequency of the oscillation movements of the two welding torches can be individually adjusted and controlled. This provides the
- 30 advantage that there are far fewer limitations in the choice of the form of the welding seam, and that the welding parameters for both torches can be optimally adjusted, whereby optimum savings are achieved in the welding time without great concessions having to be made 35 in the weld quality (defects, mechanical properties).
 - In a preferred embodiment of the method for welding together two pipes, two carriers each having two welding torches are moved in peripheral direction of the pipes,

thereby achieving a still further saving in the welding time.

The two carriers each having two welding torches can be displaced successively in the peripheral direction of 5 the pipes, but in preference each carrier is moved per welding pass over half a peripheral part of the pipes.

Each carrier is then preferably moved per welding pass in downward peripheral direction of the pipes. When particular welding processes are used, such as MIG/MAG 10 welding, downward welding can be performed at higher speed than upward welding. The total welding time in the connection of two pipes is therefore less if welding takes place in only downward direction and each carrier is returned to its starting position after each welding pass than if welding takes place downward and then upward.

The present invention likewise relates to a device for welding together two pipes or plates. The device according to the invention is characterized by two 20 welding torches lying successively in the longitudinal direction of the weld groove. A significant advantage of this device is that it is compact and thereby suitable for welding together pipes of small diameter or plates of small size.

In the case the weld groove has outward diverging walls, the device according to the invention preferably comprises means for moving at least the trailing welding torch reciprocally in transverse direction the weld groove. These means can for instance be formed by a shaft pin driven for reciprocal sliding in the carrier and connected to the welding torch.

The invention will be further elucidated hereinbelow with reference to the annexed drawings. In the drawing:

Figure 1 shows a perspective view of a preferred
35 embodiment of the device according to the invention;
Figure 2 shows on a larger scale a perspective view
of detail II of figure 1;

Figure 3 shows a front view of a carrier according to another embodiment of the invention;

Figure 4 is a schematic representation of a welding pass according to a preferred embodiment of the method 5 according to the invention; and

Figure 5 shows a cross-section of a weld groove with outward diverging walls filled using the method and device according to the invention.

Figure 1 shows a device for welding together two
10 pipes 1 which are placed coaxially against each other
while leaving clear a weld groove 2. One or more of such
welding devices can be placed on board a pipelaying
vessel to lay welding layers in the annular weld grocves
2 of a pipeline 4 displaced in arrow direction 3. For an
15 explanation of the components of the welding device shown
in figure 1 and not significant for the present invention
reference is made to the Netherlands patent application
9400742.

The welding device shown in figure 1 comprises a

20 guide ring 5 arranged round one of the two pipes 1 and
two carriers 6 for two welding torches 7 lying
successively in the longitudinal direction of weld groove
2, which carriers can be guided by guide ring 5 in
lengthwise direction of weld groove 2. According to a

25 preferred embodiment of the method, each carrier 6 is
moved per welding pass through half a peripheral part in
downward peripheral direction of the pipes. The one
carrier will thus fill the one half of the weld groove
from top to bottom and the other carrier the other half.

30 Each carrier herein provides two welding layers from top
to bottom per welding pass.

Figure 2 shows a perspective view of detail II of figure 1. On the underside of carrier 6 are situated guide wheels 8 for co-action with guide ring 5. Carrier 6 comprises a housing 24 in which is arranged a motor 9 which drives a geared drive pinion 10 which is in frictional contact with an engaging ring 11. This engaging ring 11 consisting of two halves is fixed to

guide ring 5 by means of clamping pieces 12. Motor 9 is arranged pivotally on a shaft 13 on the housing 24 of the carrier. The drive pinion 10 of motor 9 is held in contact with engaging ring 11 by means of a draw spring 5 14.

Arranged on the end face of housing 24 of carrier 6 are two torch holders 15 which each have a wedge-shaped cavity 16 for receiving a wedge 17 connected to welding torch 7. Welding torch 7 is arranged as according to 10 arrow 18 in torch holder 15, whereafter the position drawn in dashed lines in figure 2 is obtained.

For reciprocal movement of welding torches 7 in transverse direction of longitudinal groove 2, an oscillating motor 19 for each welding torch 7 is provided 15 in the housing of carrier 6. Each oscillating motor 19 drives a reciprocally slidable shaft pin 20, wherein each shaft pin 20 is guided slidably in a cylinder 21.

A lifting motor 22 is further arranged in housing 24 of carrier 6. Lifting motor 22 serves to adjust torch 20 holders 15, and thereby also welding torches 7, in radial direction. An independent height adjustment can also be provided for welding torches 7 instead of a collective height adjustment.

Figure 3 shows a front view of a carrier according to another embodiment of the invention. Welding torches 7a,7b are connected here to carrier 6 by means of clamping jaws 15. In addition, there is provided a guide ring 5 which is held at a distance from the pipes and with which guide wheels 8 are in contact. No engaging ring 11 is therefore present. The two welding torches 7a,7b placed successively in longitudinal direction of weld groove 2, indicated with arrow 23, lay two welding layers A,B in one welding pass. Because the trailing welding torch 7b lays welding layer B over the welding 35 layer A deposited by the leading welding torch 7a, the trailing welding torch 7b is placed higher in its torch holder 15 than welding torch 7a. Welding torches 7a,7b

are placed radially relative to pipes 1 so that they enclose a mutual angle.

Using figure 4 and 5 a preferred embodiment of the method according to the present invention will be 5 elucidated. Arrow A designates the welding movement of the leading welding torch 7a and arrow B that of the trailing welding torch 7b. Both welding torches perform an oscillating movement, wherein the trailing welding torch 7b is oscillated at a greater amplitude and a 10 higher frequency than the leading welding torch 7a. By means of this method a weld groove 2 is filled which has outward diverging walls. Since weld groove 2 widens towards the outside, the trailing welding torch 7b must in each welding pass deposit a wider welding layer than 15 leading welding torch 7a, and is therefore oscillated at a greater amplitude than leading welding torch 7a. In addition, the trailing welding torch 7b is preferably oscillated at a higher frequency than leading welding torch 7a in order to enable filling of the wider weld 20 groove 2 with the same quantity of material. The amplitude and frequency of the oscillation movement of each welding torch 7a,7b is adapted per welding pass to

the width of the weld groove 2 for filling.

Figure 5 shows the final result of a V-shaped weld

25 groove 2 filled in five welding passes C. Two welding
layers A,B are laid at a time per welding pass C by two
successively placed welding torches 7a,7b.

If both downward and upward welding take place, at each turning point the leading welding torch becomes the trailing welding torch and the trailing welding torch becomes the leading welding torch. It is more advantageous however to only weld downward, wherein two carriers each having two welding torches are preferably moved over half a peripheral part of the pipes, because this can take place at greater speed than upward welding and a time-saving is achieved in the total welding process.

Auste, John, James, John, Lawes, 1988, 1984, 198

Means for moving at least the trailing welding torch reciprocally in transverse direction of the weld grocve other than the shown and described oscillator motor 19 are possible, for instance a pivot arm.

The drawing shows a welding device with two carriers, wherein each carrier is provided with two welding torches. The invention is however not limited hereto. Four carriers can for instance also be applied, wherein each carrier covers a quarter peripheral part of the pipes. This can be advantageous in welding pipes with a large diameter. In addition, more than two welding torches can also be provided per carrier, wherein each welding torch can be oscillated independently with an amplitude and frequency adapted to the width of the weld groove.

A connection between two pipes can also be welded with more than one welding device, as is usual on a pipe-laying vessel.

CLAIMS

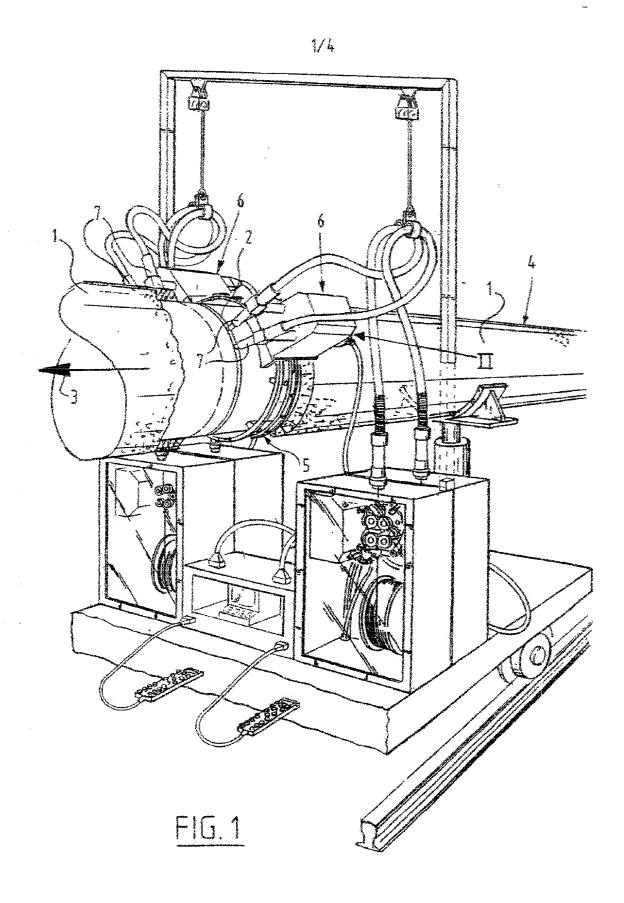

2 7 04 2001

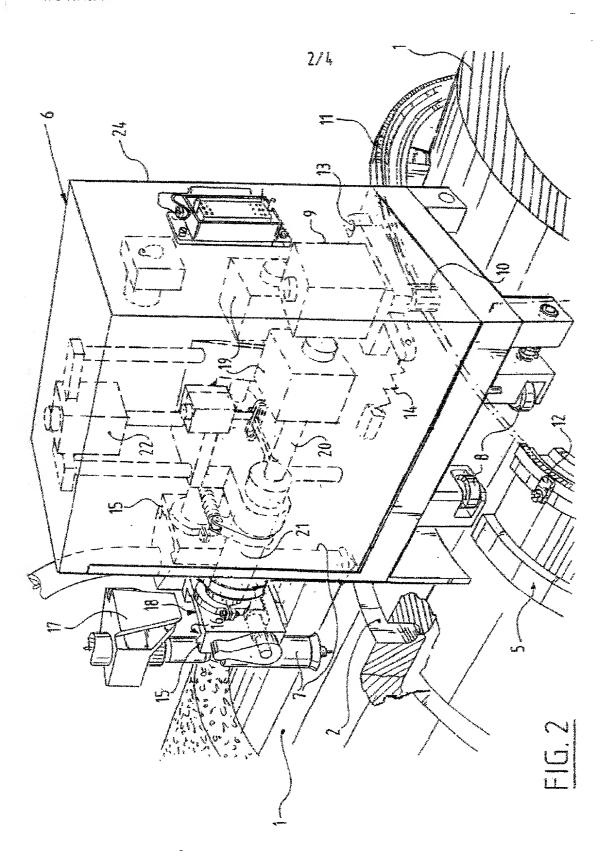

- 1. Method for welding together two bodies, for instance pipes or plates, which are placed mutually in line against each other while leaving clear a weld groove, wherein the weld groove is filled with more than 5 one welding layer by means of a welding torch moved in longitudinal direction of the weld groove, characterized in that two welding layers are laid in one welding pass by means of two welding torches placed successively at a predetermined fixed distance in the longitudinal 10 direction of the weld groove and that two carriers each having two welding torches are moved in peripheral direction of the bodies.
- 2. Method as claimed in claim 1, wherein the weld groove has outward diverging walls, characterized in that 15 at least the trailing welding torch performs an oscillating movement.
 - 3. Method as claimed in claim 2, characterized in that the trailing welding torch is oscillated at a greater amplitude than the leading welding torch.
- 20 4. Method as claimed in claim 3, characterized in that the trailing welding torch is oscillated at a frequency differing from that of the leading welding torch.
- 5. Method for welding together two pipes as claimed 25 in any of the preceding claims, characterized in that each carrier is moved per welding pass over half a peripheral part of the pipes.
- 6. Method as claimed in claim 5, characterized in that each carrier is moved per welding pass in downward 30 peripheral direction of the pipes.
- 7. Device for welding together two bodies, for instance pipes or plates, which are placed mutually in line against each other while leaving clear a weld groove, comprising a carrier for a welding torch guidable 35 in longitudinal direction of the weld groove, characterized by at least two carriers each having at

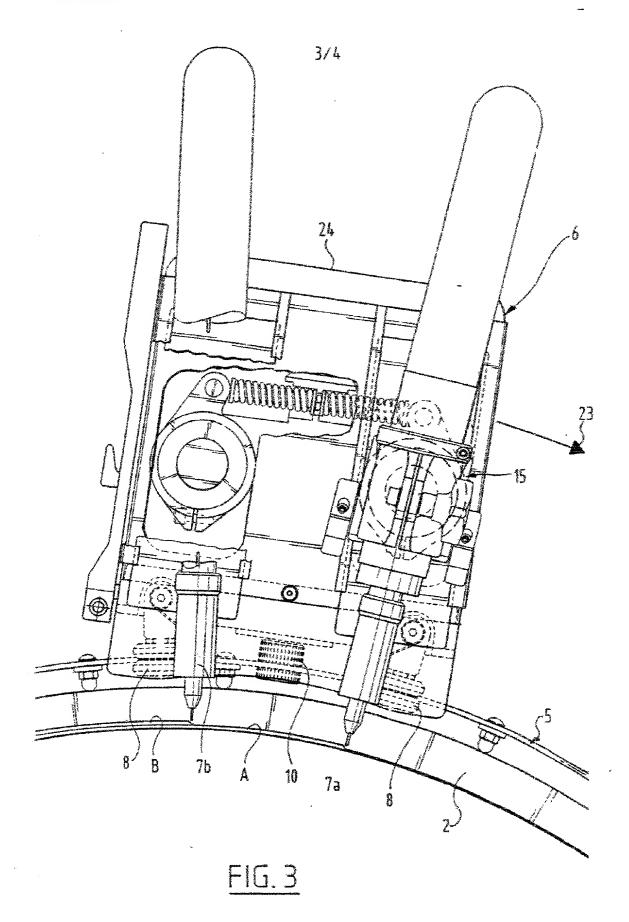

5. I VI. of Road and the first three world the effection of the first that the

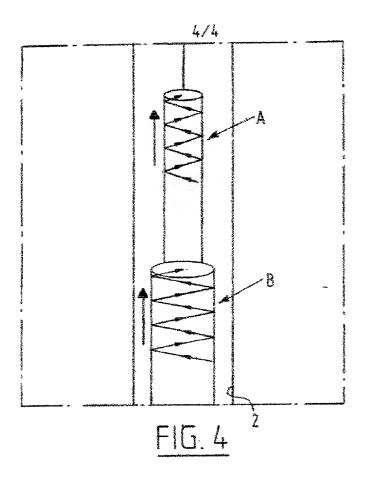

least two welding torches lying successively in the longitudinal direction of the weld groove.

- 8. Device as claimed in claim 7, wherein the weld groove has outward diverging walls, characterized by 5 means for moving at least each trailing welding torch reciprocally in transverse direction of the weld groove.
- 9. Device as claimed in claim 8, characterized in that these means are formed by a shaft pin driven for reciprocal sliding in each carrier and connected to the 10 respective welding torch.
